Circumcision remains as one of the most controversial topics in current medical practice. The most important argument against circumcision is the permanent change of anatomy, histology and function of the penis, with potential complications, which were reported to be low in developed countries, whereas the rate of complication may be up to 45% when circumcision is carried out by traditional circumcisers rather than by medically trained professionals in developing countries. In some studies reporting the complications of circumcision, primary haemorrhage was the most common (52%) complication, whereas infection, meatal stenosis, incomplete circumcision, penile oedema, glanular injury, penile adhesions, iatrogenic hypospadias and urethral injuries were also detected at different rates.

There are minor complications after circumcision that cannot be avoided even when the procedure is undertaken by specialized paediatric surgeons or urologists in properly equipped centres, especially if the child or his penis is congenitally abnormal, for example, circumcising a child with excessive suprapubic fat or a child with webbed penis or microphallus.

After practicing circumcision and managing other surgeons complications in thousands of boys for 35 years in a country like Egypt (with about 90% circumcision rate), I found parents had a great urge to do this surgery even for a handicapped or critically ill child, with a possibility for higher rate of complications. So the best way to minimize complications of male circumcision (MC) and to compete against its serious effects on male health is to standardize the MC procedure and to educate both families and physicians about the potential complications and how they could manage it early and promptly.

The spectrum of post-MC complications is so wide to be discussed, so we will just focus on both the common and the uncommon complications that usually raise a debate about their management. There are different ways to classify MC complications: early or late, minor or major, local or systemic and rare or common.

CHAPTER 10

Nonaesthetic Circumcision Scarring

MOHAMED A BAKY FAHMY, MD, FRCS

ABSTRACT
Circumcision may be undertaken as a body modification of the genitals to change the look of the penis to appeal more to certain aesthetics, but sometimes it may leave a permanent change of the natal characteristics of a body part, which will ever be subject to dispute, particularly from the cosmetic point of view. Many complications may result after nonaesthetic preputial cutting or the unhealthy healing of the circumcision wound. These complications usually manifest late, weeks or months after the procedure, and result in early family dissatisfaction and later on have a psychic impact on a man’s satisfaction with his penis and may lead to loss of self-esteem.

KEYWORDS
Incomplete circumcision; Keloid and hypertrophic scar; Paraphimosis; Penile adhesions; Phimosis; Post-circumcision lymphoedema; Post-MC concealed penis; Post-MC smegma collections; Residual prepuce; Skin bridge; Sutures marks; Untidy circumcision.

UNTIDY CIRCUMCISION (UGLY CIRCUMCISION SCAR)

Circumcision is a procedure that will alter the entire anatomy and the look of the penis, which itself carries a countless variations among populations, so it is extremely difficult to standardize the shape and appearance of the penis after this operation. Different studies concluded with a diverse opinion about the aesthetic look of the penis after MC.1

Cosmetic results were compared and rated by the Patient and Observer Scar Assessment Scale (POSAS)² as the following:
Good: Linear scar with minimal or no puckering.
Average: Linear scar with puckering of the surrounding skin without depression.
Poor: Severe puckering and depressed irregular scar.

Fig. 10.1 represents my own opinion about the desirable scar after circumcision by dissection method, with a thin circular scar around the coronal sulcus with a narrow rim of inner prepuce left, a preserved frenulum and adequate penile skin to allow, later on, the erected penis to stretch smoothly.

Irregularity of the healed wound after MC, which may result in an untidy scar, is usually due to heavy suturing, post-MC infection, haematoma formation or leaving the compression bandage for a longer time after circumcision. Such cases are different from cases of incomplete circumcision, which had a normal scar edge but excess amount of residual prepuce, and also cases of localized skin bridges.³

Excessive scarring at the circumcision edge may be due to uneven incision lines, which usually occur in guillotine method and free-handed sleeve circumcision by unexperienced surgeons. Such cases may deserve correction and proper reconstruction under general anaesthesia by a reconstructive surgeon with a good experience in penile surgery, as any attempt to repair such cases early by an inexperienced surgeon may result
in more skin loss, penile concealment and deformities (Fig. 10.2).

Unequally inner or outer preputial cutting may result in excess skin or mucous membrane in one side of the healed scar. This may be encountered in either free-handed or guillotine method, but uncommon with the use of the Gomco and Plastibell methods (Figs. 10.3 and 10.4).

Bad mucosal healing, irregular circumcision scar and suture sinus tracts result collectively in a bad cosmesis of the scarring around the corneal sulcus (Fig. 10.5).

Glans injury or cauterization by diathermy during MC, or a post-circumcision infection, may result in isolated scarring and disfigurement of the glans penis, and such cases are extremely difficult to repair (Fig. 10.6).

The whole concept of an aesthetic prepuce will be discussed in Chapter 11.

PENILE ADHESIONS

Penile adhesion is a broad term for different pathologic condition. The most common one is the localized form of skin bridge. Penile adhesions are a relatively common complication of circumcision, especially at neonatal age, and are the primary reasons for reoperation in the late postoperative period.

Predisposing Factors

Adhesions are more likely in children with an increased weight for length percentile, in children with a large suprapubic fat pad with abnormal dartos attachments to the skin and in cases of pre-existing penoscrotal webbing or ventral penile skin deficiency. Adhesions are also common in neonatal MC, as the inner prepuce
is physiologically adherent to the glans, and any forcible attempt to separate it will result in a denuded glandular surface, which will easily heal with fibrous scarring with the surrounding penile skin. Different forms of penile adhesions may follow post-MC infectious complications, especially bacterial balanitis; also, balanitis xerotica obliterans (BXO) cases after MC may be associated or complicated with severe penile adhesions, especially if the circumcision wound is untidy (Fig. 10.7).

Adhesions could be seen at different levels and between different parts of the penis:

- Adhesions between excess remnants of mucous membrane (inner preputial layer) and the glans penis, which may be partial or complete forming a ring around the glans (Fig. 10.8).
- Complete adhesions of the redundant cut edges of the prepuce with the raw surface of the glans, which may eventually lead to cicatricial phimosis (Fig. 10.9).
- Adhesions between a localized raw surface of the glans and penile skin forming different forms of skin bridging between the penile shaft and the glans penis, crossing the coronal sulcus (Fig. 10.10).

All these adhesions of the mucosal collar to the glans are avoidable by gentle preputial retraction, meticulous tissue handling and use of barrier ointments in the early post-operative period.

**FIG. 10.3** Unequal scar with excess outer and inner preputial layers at the left side.
SKIN BRIDGES

Sometimes a localized area of adhesion results in the formation of well-formed excess skin bridges between the skin of the penile shaft and the glans penis (Fig. 10.10). These epithelialized adhesions can lead to penile chordee, torsion, and later on, it may result in a painful erection due to tethering of the erected penis. Skin bridges in the ventral penile surface are usually more symptomatic than the dorsal and lateral ones. The abnormal scarring will also make the circumcised penis looks ugly with an obvious disfigurement (Fig. 10.11).

Smegma often accumulates under those skin bridges, and it may form a well-capsulated cyst (Fig. 10.12).

Skin bridges could be seen as a single area of wedge like skin creeping over the glans with different sizes at one side, or multiple scars of different shapes around the glans (Figs. 10.13 and 10.14).

Excess redundant skin after circumcision, physiologic retraction of the penis due to a suprapubic fat pad and diaper irritation of the penis may be predisposing factors.

Incidence

How such this problems arise is not completely clear, as true incidence is difficult to estimate. But some authors reported that skin bridges accounted for nearly 30% of the late complications. The rate of complications usually decreases with age, owing to the epithelial separation of the adhesions (71% of infants, 28% of 1–5 year old children, 8% of 1–9 year old children and 2% of children older than 9 years). 4

FIG. 10.4 An excess inner preputial layer at the right side of the glans.
FIG. 10.5 Prominent stitch marks along the scar of circumcision.

FIG. 10.6 Multiple glandular injuries leading to disfigurement.
Treatment
This complication could be avoided by completely freeing the inner preputial layer from the glans at the time of circumcision; also, if any glanular abrasions, injury or ulcer is detected during MC, it should be dressed and managed properly until complete healing to avoid the natural cohesion between the denuded area of the glans and the penile skin. Use of low-dose corticosteroids has been relatively unsuccessful in lysing these well-formed adhesions. The adhesions can be excised in the office with the application of local anaesthesia or in the operating room with the use of general or regional anaesthesia by suturing the glandular and shaft defects with fine absorbable sutures (Fig. 10.15).

In my opinion, routine suturing of both preputial layers with fine stitches either continuously or with interruptions, even in neonatal MC, will protect the healing incision from such complications.

INCOMPLETE CIRCUMCISION
Nomenclature: Residual prepuce, inadequate circumcision or excess foreskin.

The high degree of variability in the appearance of penis after MC could not be related to the technique...
used or to the physician using it. When operating on an infantile penis, the surgeon cannot adequately judge the appropriate amount of tissue to remove because the penis will change considerably as the child ages, such that a small difference at the time of surgery may translate into a large difference in the adult circumcised penis. Any one dealing with penile anomalies can recognize the diversity and wide variation in the normal anatomy of different penile structures because many neonates may have a very long prepuce, which is called ‘akroposthia’, and some may have a deficient prepuce, with an exposed distal glans without preputial retraction, so the amount of prepuce to be removed in MC should be tailored for each baby according to the length of his prepuce. This is extremely difficult to achieve in mass circumcision or even in a hospital with a high

**FIG. 10.8** Extensive penile adhesion between the circumcision scar and the glans, forming a ring around the glans, with marked disfigurement.
number of cases. To date, there have been no published studies showing the ability of a circumciser to predict the later appearance of the penis.\textsuperscript{3}

According to the previous studies, between 1% and 9.5% of boys circumcised at birth will have the procedure revised or redone and 2.8% of parents will complain of the cosmetic appearance.\textsuperscript{3}

Leaving a short inner prepuce is achievable in open sleeve and clamp techniques (Gomco and others), but it is not possible in the traditional guillotine-type circumcision, which leaves a very long inner prepuce with a circumcision line placed in almost the middle of the penile shaft (Fig. 10.16). Unfortunately, this is still the most common technique performed by nonmedical personnel in large parts of the world.

The inner foreskin and outer foreskin are separate entities, and not the opposite sides of a single layer of tissue. They are not attached to each other and in consequence are mobile with respect to each other. Thus it is possible to remove unequal amounts of the two layers. Understanding this point is crucial for recognition of a different circumcision styles.

If we can exclude other complications, the penile looks after different techniques of MC may be one of these two common styles:

- MC style that retained the inner foreskin (the ‘high’ style). The circumcision scar line of a man with the high style will be partway up his penis (Fig. 10.16). If the scar is moving freely without tightness, it is called high loose, otherwise it is a high tight one. Of course,

\textbf{FIG. 10.9} Penile adhesions forming a scar ring with the glans around the urinary meatus, which may result in cicatricial phimosis.
these cases should be differentiated from cases of sever skin loss, which may heal with intense fibrosis.

- MC style that removed the inner foreskin (the ‘low’ style): The circumcision scar line of a man with the low style will be close to the rim of his glans (Fig. 10.17). If the scar ring is tight, it may be problematic and may be considered as a concealed penis (CP) or even an acquired phimosis. A loose scar is an acceptable form, but it may be an indication for MC redo according to some parents’ wishes. So the circumcised scar could be classified as
  - High loose
  - High tight
  - Low loose
  - Low tight

The amount of penile skin excised can also lead to many other complications, as insufficient or asymmetric prepuce excision can result in a cosmetic and social dilemma for the parents and the child, especially when the child gets older (Fig. 10.2).

A circumcision that is too loose may not leave the glans completely uncovered but it will, in other words, be a partial circumcision, and this is not in itself a problem but it may not meet parental or religious expectations. However, there is one important exception, if the scar can mobilize in front of the corona then it will shrink and create secondary phimosis, which requires recircumcision. If a partial circumcision is deliberately chosen then the best approach is to remove the inner foreskin completely, so that the scar will be in the sulcus. At puberty the penis will usually outgrow the skin and leave the glans exposed, as the degree of skin covering the glans after neonatal circumcision peaks at 6 months of age.
Management

Unlike neonatal circumcision, circumcision revision requires general anaesthesia, for which several techniques have been described. Excessive skin excision can result in penile chordee, torsion and lateral deviation. These conditions, if necessary to repair, may require penile skin flaps or Z-plasty for closure.

Excessive skin removal can also result in a trapped penis from a cicatricial scar. The trapped penis can be managed with betamethasone conservatively, vertical relaxation incision and then a formal repair. The use of 0.05% betamethasone in conjunction with manual retraction in children with a trapped penis due to a dense cicatrix of the residual foreskin distal to the glans has a 79% success in softening the cicatrix with easy exposure of the glans or mild persistence of the cicatrix amenable to vertical relaxation incision.5

While many people favour retaining a lot of inner foreskin, this can sometimes cause problems. The inner skin is very thin and stretchable, and if there happens to be a lot of postoperative swelling, it can permanently stretch the skin, leaving it loose and puffy. This has no effect on penile function, but it can appear unsightly (Fig. 10.18).

If the physician succeeds to convince the parents (or sometimes the circumcised adult) not to revise the circumcision in cases of low or incomplete MC, special attention should be paid to the retained part of the prepuce. Generally, the circumcised penis requires more care than the intact penis, especially during the first
3 years of life; any skin covering the glans in circumcised boys should be retracted and cleaned to prevent adhesions and debris accumulation.

In contrast to the general belief that smegma is not present, or at least not accumulated, in circumcised boys, we encountered many circumcised babies with the same smegma accumulation and configuration as in the intact ones, especially in those children with low loose type of circumcision. So all the adverse effects of smegma will be seen in an adult with a retained long prepuce after circumcision (Fig. 10.19).

POST-MALE CIRCUMCISION CONCEALED PENIS
Generally, CP refers to an anomaly such that the penis appears to be short, even though its length is normal. CP may be divided into three groups according to the Maizels classification, which is based on the aetiologic mechanism: buried penis, webbed penis and trapped penis.

One or more mechanisms may contribute to concealment in each case:
- Buried penis describes a condition in which a penis remains under the level of pubic skin because of the excessive suprapubic fat or the loose attachment of penile skin to the dartos.
- Webbed penis is a condition in which there is extra skin between the scrotal raphe and distal penis, obscuring the penoscrotal angle.
- Trapped penis refers to a condition in which a normal penis is depressed under the skin following a surgical procedure, generally circumcision, and looks concealed, and this type is our main concern herein (Fig. 10.20).

Williams et al. reported a rate of 9% CP among those applying for routine circumcision. The same study reported a 63% incidence of CP among those applying...
for circumcision revision (26% trapped penis and 37% insufficient circumcision). It is possible that one may refrain from excising sufficient prepuce in order to avoid a more complicated picture in a case with partial CP and as a result insufficient circumcision may take place. In a baby with CP, generous excision of the penile skin in an effort to make the penis visible usually leads to a crippled problem of trapped penis, with almost no local penile skin surrounding the penis, which will require flaps or grafts for correction.

This complication is commonly seen in overweight children or in those with extensive suprapubic fat and is expected to associate cases of microphallus and webbed penis.

Post-MC CPs could be classified into complete and partial concealment.

**Complete**
This is commonly seen in neonatal circumcision in which the penis is completely hidden and covered by either the scarred penile skin or the scarred preputial remnants (Fig. 10.20).

**Partial**
In this condition, the glans penis is visible but the penile shaft is partially covered by the scarred skin, and this is usually seen in older children (Fig. 10.21).
Penile entrapment by the circumcision scar may be complicated by an ascending urinary tract infection (UTI), balanitis and may lead to a cicatricial phimosis.

In children with a secondary CP, but without phimosis, observation may be an option, as the cosmetic appearance tends to improve with age and surgery should be delayed until the child is at least 3 years of age. Borsellino et al. reported that a staged revision surgery was required in a majority of their cases because the penile shaft skin was also excised along with the prepuce.

**POST-MALE CIRCUMCISION PHIMOSIS**

Nomenclature: Cicatricial phimosis, acquired phimosis, preputial stenosis.

Post-MC phimosis is a sort of penile adhesion, with extensive scarring distal to the urinary meatus, covering the glans penis completely with inability to retract the preputial remnants proximally (Fig. 10.22).

When operating on the infantile penis, the surgeon cannot adequately judge the appropriate amount of tissue to remove because the penis will change considerably as the child ages, such that a small difference at
FIG. 10.15 Surgically excised skin bridges, and fine stitching of the preputial and glandular defects.

FIG. 10.16 High loose male circumcision with excess inner prepuce.
the time of surgery may translate into a large difference in the adult circumcised penis. Phimosis with a trapped penis is an infrequent but important complication of circumcision. This condition is more likely to occur in older infants and those with poor attachment of the penile skin to the shaft.

Incidences of 0.32%, 0.4% and 1% have been reported for preputial stenosis resulting from neonatal circumcision. Although the exact incidence of preputial stenosis (phimosis) in boys with intact penis is unknown, it is most likely between 0.9% and 1.9%.\(^\text{10}\)

Penile inflammation (balanitis) may be more common in circumcised boys with preputial stenosis than in uncircumcised children with phimosis. The common finding of subpreputial debris in circumcised infants may reflect inadequate hygiene; these debris usually consisted of lint, dirt, talcum powder, stool and detritus. The association between subpreputial debris

\begin{figure}[h]
\centering
\includegraphics[width=\textwidth]{image.png}
\caption{Low loose male circumcision with excess of both the preputial layers, but without constriction.}
\end{figure}
FIG. 10.18 Incomplete male circumcision, with a long inner prepuce, looks puffy and inflamed.

FIG. 10.19 A smegma collection with dirt in a circumcised boy.
and coronal adhesions implicates poor hygiene as a possible cause. In the normal penis, muscle fibres are arranged in a whorl to form a sphincter that keeps unwanted contaminants out. Urine swirling under the prepuce in a normal infant before expulsion flushes any contaminants from the subpreputial space and may explain the paucity of findings in this population. Subpreputial debris may have been under-reported in young boys with intact penis because forcible retraction of the foreskin, which is a harmful practice, was not frequently performed. Difficult micturition is a common symptom, and UTI and even urinary retention may complicate the case (Fig. 10.23).

**Treatment**

Unlike the treatment of primary phimosis, application of local corticosteroid cream does not cause separation of secondary glanular adhesions after circumcision. Early recognition allows outpatient treatment with excellent results, avoiding operative intervention with general anaesthesia, by genital separation of the scarred tissue from the glans and widening of the stenosed hiatus.
In difficult and neglected cases, repair is scheduled electively under general anaesthesia and is best started by marking the part of skin to be removed precisely and a proximal incision applied, removing the redundant skin and preputial membrane as separate layers starting from up and going down to the meatus. But great caution should be exerted to avoid excessive skin removal, and the technique can be accomplished by fine stitching of the penile skin with the internal preputial remnant rim (Figs. 10.24 and 10.25).

A special entity may be encountered in adults suffering from BXO who were managed by circumcision as a treatment modality. As a few cases may develop cicatricial phimosis if the prepuce is removed incompletely and balanitis recurs, adhesions between the glans and the prepuce are also common and these adhesions are difficult or impossible to separate. Such cases could be managed by leaving a fine layer of dartos covering the glans rather than denuding it, and the residual epithelial cells in this layer are left to recover the glans over the following weeks.

**PARAPHIMOSIS**

Paraphimosis is a true urologic emergency that occurs in uncircumcised men when the foreskin becomes trapped behind the corona of the glans penis, which can lead to strangulation of the glans as well as painful vascular compromise, distal venous engorgement, oedema and even glandular necrosis. Phimosis, by comparison, is
the condition in which the foreskin is unable to be retracted behind the glans penis (Fig. 10.26).

Paraphimosis could happen because boys have been encouraged to retract the foreskin for physiologic phimosis by parents or medical staff.

Paraphimosis commonly occurs iatrogenically when the foreskin is retracted for cleaning, for placement of a urinary catheter, during a procedure such as cystoscopy or during penile examination. Iatrogenic paraphimosis is an acute complication of MC in neonates and children when the circumciser fails to reposition the prepuce after initial retraction during the procedure. This complication is not related to the aesthetic complication but is discussed herein for its relation to phimosis.

**Incidence**

In uncircumcised children, aged 4 months to 12 years, with foreskin problems, paraphimosis (0.2%) is less common than other penile disorders such as balanitis (5.9%), irritation (3.6%), penile adhesions (1.5%) and phimosis (2.6%).

---

**FIG. 10.22** Post-circumcision cicatricial phimosis.
There is no estimation of the incidence of paraphimosis, which complicates the procedure of MC, but we dealt with many cases referred from the primary care centres with a strangulated preputial hiatus behind the coronal sulcus after different procedures of circumcision.

Factors that may predispose to paraphimosis include:

- Forcible retraction of prepuce, while the baby had different grades of phimosis.
- Babies with congenitally tight preputial opening without inflammation.
- Neonatal circumcision by inexperienced personnel.
- It is not a rare complication during circumcision of children with blood-related diseases (Fig. 10.27).
- Paraphimosis caused by dislodgement of the plastic ring represents 41.8% of complications among children circumcised by the Plastibell technique, a complication that was responsible for the highest rate of reoperation.\textsuperscript{14}

**Sequelae**

Paraphimosis encountered during routine MC is a controllable complication and easy to be managed without any sequel, if treated immediately or referred to specialized centres. But glans penis ischaemia or necrosis caused by paraphimosis is a rare complication of a urologic emergency, with a few cases were reported in the literature.\textsuperscript{13}

**Management**

In most instances, manual compression can reduce the preputial oedema within the first few hours; however,
enthusiastic attempts without adequate analgesia and sedation should be avoided, as they are distressing, are likely to fail and may make further examination or treatment interventions very difficult. Various techniques are described to treat this condition, including applying granulated sugar to the penis, adding multiple punctures to the oedematous foreskin before compression, injecting hyaluronidase beneath the narrow band to release it and wrapping the distal penis in a saline-solution-soaked gauze swab and squeezing gently but firmly for 5–10 min. Thereafter, physicians are supposed to push forcefully on the glans with the thumbs, while pulling the foreskin with the fingers. However, an emergency dorsal slit may be necessary in late cases. Generally, some authors advise completion of circumcision for paraphimosis, whereas others insist that circumcision is not advisable and could be postponed or deferred as the foreskin is oedematous and other major injuries may supervene.\textsuperscript{16}

**KELOID FORMATION**

Since Warwick and Dickson\textsuperscript{17} firstly described their experiences with a post-circumcision keloid in 1993, only a few cases have been reported so far, but it is expected that many cases may escape proper diagnosis and reporting.

Keloids are benign, hyperproliferative scar tissue growths characterized by excessive deposition of collagen and other extracellular matrix components. Although the exact pathogenetic mechanisms are still unknown, extracellular matrix abnormalities, aberrant collagen turnover, mechanical tension and genetic immune dysfunction have all been proposed as pathogenetic hypotheses. In addition, fibroblast cells derived from keloid tissue display an increased proliferation and density, among many other characteristics.

The most likely cause of post-MC keloid was the postoperative dehiscence resulting in prolonged wound healing in a genetically predisposed individual.
FIG. 10.25 After removing the excess constricting skin in cicatricial phimosis, fine absorbable stitches are applied.

FIG. 10.26 A case of paraphimosis with an oedematous constricted prepuce behind the coronal sulcus.
Although keloid formation has been documented to be most frequent in patients between the ages of 15 and 45 years, only a few cases were reported below 12 years of age.\(^\text{18}\)

Clinically a keloid is an abnormal development consisting of a raised, firm, thickened, red piece of scar tissue. Such abnormal scar at the site of circumcision creates a grotesque deformation of the organ, with obstruction of its function. Different forms of keloid, either localized or circumferential, had been reported after MC (Fig. 10.28).

Like other keloids of the body, the post-MC keloid seems to be more common in the black races. The predisposing factors are prolonged wound healing, foreign body implant during circumcision and rough manipulation of the delicate penile skin.

**Fig. 10.27** A haemophilic child with an oedematous prepuce after reduction of paraphimosis.
Less extensive prominent scars can occur with severe fibrosis around the coronal sulcus, and mild forms of hypertrophic scar of the healing wound after circumcision are not rare, but uncommonly reported. We diagnosed a few cases with a localized area of hypertrophic scar, especially in older children; such cases may respond to prolonged use of a potent corticosteroid, without a need for surgical intervention (Fig. 10.29).

Keloid excision with or without skin grafting is indicated as a different postoperative measure to avoid recurrence of a keloid tissue. Radiation therapy is contraindicated in children and is not desirable for penile keloids because of the close proximity of germ cells. Intralesional corticosteroid injection decreases fibroblast proliferation, collagen synthesis and suppresses pro-inflammatory mediators. The most commonly
used drug for steroid injection is triamcinolone acetonide suspension at a dose of 5–10 mg/mL, which is injected intraleisonally.

**SUTURE MARKS**

Post-MC suture marks are sometimes termed as spitting sutures, which are detected weeks to months after surgery if the body rejects the sutures (again, from the stitches not absorbed as intended) and attempts to remove them by pushing the stitches out to the surface of the skin. Sutures that migrate in this way have been known to be the source of additional problems, such as a penile disfigurement from the untidy stitches marks or fibrosis (Fig. 10.5).

It is recommended for skin closure after MC to be done with the most delicate rapidly absorbable sutures. As the inner foreskin of newborns and infants is fragile,
6/0 or 7/0 quickly absorbable materials such as polyglactin or polyglecaprone can be used. For older kids and adults, 5/0 quickly absorbable materials may be used. Using medical cyanoacrylate is a good alternative to stitching. It avoids permanent suture marks and suture tunnels that may be problematic. Meticulous haemostasis is vital before cyanoacrylate application. Subcuticular (separate or continuous) suturing, which has similar advantages, can also be used by giving some more time and effort.

Thick and slowly absorbable materials cause permanent suture tracts, which are a common sequel, resulting in disfigurement of the MC scar; very rarely small sinuses may be encountered long time after circumcision at the site of nonabsorbable stitches (Fig. 10.30).

A small stitch granuloma with or without smegma collection may also be seen with the stitch remnants (Fig. 10.31).

**POST-MALE CIRCUMCISION SMEGMA COLLECTION**

**Definition:** The word smegma is of Greek origin meaning soap or an ointment.

Smegmoma: Preputial smegma cyst.

Smegmaliths: Pieces of hard contaminated and retained smegma.

Smegma has a characteristic slimy odour and is composed of epithelial debris, fat and proteins. It has mixed bacterial flora, including the smegma bacillus (*Mycobacterium smegmatis*) in 50% of man.

Smegma is the natural secretion of the prepuce, like other body secretions, such as earwax. So it is not harmful by itself, unless it is complicated by other pathogens, bacterial colonization, viral overgrowth or a combination of organisms. Smegma collection is usually associated with phimosis and different forms of balanitis or balanoposthitis.

Smegma secretion and distribution had a great variation between individuals and between different ages without a clear explanation. Wright states that smegma is produced from minute microscopic protrusions of the mucosal surface of the foreskin and that living cells constantly grow towards the surface, undergo fatty degeneration, separate off and form smegma.

Smegma should be cleaned frequently in uncircumcised boys by the mother during childhood and by the boy himself later on. Circumcised boys, especially those with excess skin remnants, may have a marked smegma
secretion and attention should be paid to clean it as in uncircumcised boys (Fig. 10.19).

During circumcision, smegma should be cleaned and removed meticulously with saline wash, otherwise any retained small pieces will be entrapped and will accumulate between the edges of the incised prepuce and result in different forms of cysts of smegma, which may become large and will lead to different complications.

**Smegma Cyst**

Aggregation of smegma in circumcised children is not rare and may present alone without any other complications or in association with skin bridges (Fig. 10.12) or with stitch granuloma (Fig. 10.31) as a yellowish cystic or doughy swelling of different sizes at the cut edges of the prepuce (Fig. 10.32). Sometimes the swelling may become larger, disfiguring the penis (Fig. 10.33). It is usually presented as a single swelling, but cases with multiple small cysts are not rare (Fig. 10.34).

Smegma, produced under the foreskin, is made of 27% fat and 13% protein and contributes to the higher occurrence of *Malassezia* fungal species in uncircumcised versus circumcised men (49% vs. 7%). The frequency of yeast colonization in smegma is around 11%.21

It is considered as an inclusion cyst, and if seen at the ventral surface of the penis, or along the median raphe, it should be differentiated from other rare true penile cysts, such as parameatal cysts, mucoid cysts or median raphe cysts22 (Fig. 10.35).

These cysts are liable to irritation, traumatic rupture and infection with abscess formation. This complication is avoidable, but once diagnosed, careful excision under general or regional anaesthesia, with meticulous penile skin closure, is indicated and will avoid recurrence.23

FIG. 10.33 A large smegma cyst at the dorsum of the penis.
POST-CIRCUMCISION PENILE LYMPHOEDEMA

Generally, lymphoedema of the external genitalia is an unusual problem in countries where endemic filariasis is rarely experienced. The abnormal retention of lymphatic fluid in subcutaneous tissue as a result of lymphatic obstruction can cause swelling, pain, disfigurement, difficulties in urination and later on a decrease in potency. Lymphoedema may be idiopathic or secondary to inflammation, surgical incision, neoplasm, radiation, hypoproteinemia, venous thrombosis and other medical conditions.

Preputial cutting severs the lymph vessels of the penile skin, and it may interrupt the circulation of lymph and sometimes cause different grades of penile lymphoedema, which is a painful, disfiguring condition in which the remaining skin of the penis swells with trapped lymph fluid. A few cases had been reported in the literature complicating MC, but we diagnosed a few cases with a variable extension and different forms of presentations (Fig. 10.36).

On the other hand, cutaneous lymphangiectasia (CL) or acquired lymphangioma is another lymphatic malformation, mostly congenital, whereas acquired CL occurs because of the obstruction of deeper lymphatic vessels secondary to other causes. It is characterized by the presence of a circumscribed eruption of thin-walled, translucent vesicles and ranges from clear, fluid-filled blisters to smooth, flesh-coloured nodules, sometimes with a coexisting lymphoedema. Mostly, CL is asymptomatic but pruritus, burning or painful lesion and sometimes a foul-smelling viscous discharge may also occur. We have only one case diagnosed as
FIG. 10.35 Post-circumcision smegma cyst in the ventral penile surface looks like a mucoid penile cyst.

FIG. 10.36 A localized lymphoedema of excess inner prepuce after guillotine male circumcision.
Having CL in a previously normal adolescent, who was circumcised at the age of 10 years under general anaesthesia and developed CL at the scar of circumcision 2 months after the procedure, with progressive extension of the characteristic skin lesions in the penile and scrotal skin, which resulted in an ugly scar at the coronal sulcus; histopathologic findings confirmed the diagnosis of CL (Fig. 10.37).

Pathophysiology
There are two lymphatic systems in the penis: the superficial system and the deep system. The superficial system drains the prepuce and the skin of the penis, and it flows into the superomedial zone of the superficial inguinal nodes. The deep system drains the glans, runs beneath the deep fascia and flows both directly into the pelvic nodes and the superficial inguinal nodes. These anatomic structures can explain the discrepancy between the severely involved penile skin and the intact glans, as observed in Fig. 10.38, where the extensive excision of penile skin during MC results in lymphoedema of the remnant penile and scrotal skin, while the glans is minimally affected (Fig. 10.38).

The lymphatic vessels of the superficial dermal plexus drain a fixed area of skin through the vertical collecting lymphatics to the deep plexus. The damage to deep lymphatic vessels leads to back pressure and dermal backflow, with subsequent dilatation of the upper dermal lymphatics. Because circumferential excision of the penile skin above the deep fascia does not interfere with the deep lymphatic system, secondary penile lymphoedema is unusual.

Diagnosis
The diagnosis is mainly clinical aided by the histopathologic finding of dilated lymphatics in the dermis during surgical treatment.

Post-MC lymphoedema could be classified according to its extension into

![Fig. 10.37](image)

**Fig. 10.37** A case of cutaneous lymphangiectasia complicating adult male circumcision, with the main brunt of the lesion at the circumcision scar and with an extension to the scrotal skin.
• lymphoedema of the excess remnant prepuce (Fig. 10.36),
• penile lymphoedema,
• penoscrotal lymphoedema (Figs. 10.38 and 10.39),
• CL (Fig. 10.37).

**Differential Diagnosis**

Lymphoedema detected after MC should be differentiated from cases of congenital primary lymphoedema (lymphoedema praecox), which is a rare anomaly and may be present since birth or may develop later but unrecognized before performing MC and only manifested or could be aggravated after the surgical trauma of MC, as circumcision may have initiated and accelerated the lymphatic obstruction leading to oedema\(^27\) (Fig. 10.39).

Post-MC lymphoedema should also be differentiated from cases of angioneurotic oedema, which may accidentally follow MC due to local or systemic causes, such as insect bites or drug eruption, in the latter case, the condition usually affects other organs with itching and responding early to antihistaminic medications\(^28\) (Fig. 10.40).

Lymphangiectasia has to be differentiated from herpes genitalis, genital warts and molluscum contagiosum.
Treatment

Regardless of the cause, lymphoedema is not fatal, but its chronic nature makes the patient miserable. Treatment should be directed towards the cause and aimed for reduction of the underlying oedema and control of infection.

Management of isolated penile lymphoedema is challenging, and medical treatments include the use of oral antibiotics for identified infectious pathogens, empirical antibiotics for presumed subacute genital infections, oral steroids and topical steroid application limited to areas with cutaneous lesions. Although various methods of lymphangio- plasty have been described by several authors, they are technically difficult and unreliable and are therefore not often performed. The most common approach is excision of all the involved skin and subcutaneous tissue to the level of Buck fascia followed by coverage of the genitalia with local tissue flaps or skin grafts.

ABSTRACT

In North America, it is fairly common to imagine the uncircumcised, or the intact, penis as ‘ugly’. Numerous examples can be found in popular cultures that refer to the uncircumcised penis and its foreskin as abject, disgusting, dirty, etc. As such, the circumcised penis has become something of a norm in North America, especially the United States where in the words of one scholar, ‘circumcision is consistent with American notions of good parenting’. Likewise, the foreskin has seemingly disappeared form medical textbooks, as noted by J.R. Taylor, A.P. Lockwood and A.J. Taylor: ‘The current tendency to eliminate the prepuce from anatomy textbooks reflects the popular emphasis on the glans; perhaps the wrinkling and pleating of the retracted prepuce, like unwanted hair, is an affront to good taste or simply superfluous to requirements.’

What all this assumes, of course, is that the circumcised men are aesthetically superior and that all circumcisions will necessarily result in this aesthetic improvement — in this logic, then, there are never any mistakes or accidents. However, as has been well documented, circumcision complications do arise, and sometimes they leave the penis with scars, which can become an aesthetic concern; indeed, the correction, as it were, can become a new problem. This chapter thus considers the ugliness of the circumcised penis, especially when complications arise.

KEYWORDS
Aesthetics; Circumcision; Foreskin; Scars.

In North America, it is fairly common to imagine that the uncircumcised penis is ‘ugly’. Numerous examples can be found in popular cultures that refer to the uncircumcised penis and its foreskin as abject, disgusting and dirty. As such, the circumcised penis has become something of a norm in North America, especially in the United States where ‘circumcision is consistent with the American notions of good parenting’. Indeed, as noted by J.R. Taylor, A.P. Lockwood and A.J. Taylor, the foreskin has disappeared from medical textbooks: ‘The current tendency to eliminate the prepuce from anatomy textbooks reflects the popular emphasis on the glans; perhaps the wrinkling and pleating of the retracted prepuce, like unwanted hair, is an affront to good taste or simply superfluous to requirements.’

What all this assumes, of course, is that the circumcised penis is aesthetically superior and that all circumcisions will necessarily result in this same aesthetic improvement — in this logic, then, there are never any mistakes or accidents. However, as has been well-documented, circumcision complications do arise, and sometimes they leave the penis with scars, which can become an aesthetic concern; indeed, the correction, as it were, can become a new problem. This chapter thus considers the ugliness of the circumcised penis, especially when complications arise.

A NOTE ON TERMINOLOGY

I use the term ‘uncircumcised’ to refer to the penis that has not been circumcised. I recognize, however, that this terminology is problematic for some, especially those in the anti-circumcision community. Wallace has proposed that we ought to use three distinct terms to refer to different types of penises: ‘intact’ (those in the natural state), ‘circumcised’ (those with the prepuce removed), and ‘uncircumcised’ (those with a restored prepuce or pseudo-prepuce). I recognize that for Wallace these distinctions are important, and he is not alone. In one article published in the Australian Forum, a man explains, ‘I really resent the calling of a man who has a natural penis with foreskin as “uncircumcised” as if it was something that had to be done!’ Likewise, Lander explains that using the term ‘uncircumcised’ is ‘irrational’ because it requires that one ‘define the normal as “not operated upon”’ and thus argues that ‘the normal male should be addressed as such, or referred to as...’
“intact”. However, it seems to me that ‘uncircumcised’ is the commonly accepted terminology for a penis that has retained its foreskin, even if there are a growing number of men who would prefer a term such as ‘intact’ or ‘natural’. Moreover, what is missing from Wallace’s typologies is the case of aposthia, in which, the neonate is born without a foreskin. Regardless, what should be clear is that the profession should respect the term or terms that an individual uses for himself.

A NOTE ON APPROACH
This article is established in the social sciences and humanities, rather than the medical sciences; however, I believe it contributes to both theses and fields of inquiry and practice. Just as I have done in my research on the uncircumcised penis, I draw on a range of sources that may be unfamiliar to those trained in the medical sciences, or even sources that might never be quoted in the medical sciences, for any number of reasons. As a scholar, I am as likely to work with an ethnographic study as I am to work with a sex advice column in a popular magazine. I think it is important that wherever we come from that we are engaging with a wide range of materials because we likely will encounter a wide range of perspectives in the people we engage with, the audiences with whom we speak and the patients who are cared for by the medical profession.

CIRCUMCISION
Circumcision is perhaps the world’s first surgery, and most would likely agree that it is, at the very least, probably one of the oldest of all surgical procedures. Incidentally, decircumcision, or foreskin restoration, is likely the oldest, and thus, the first aesthetic surgery as Gilman has argued. Hutson notes, ‘circumcision has a long history in ancient societies of the Middle East, and is likely to have arisen as an early public health measure for preventing recurrent balanitis, caused by sand accumulating under the foreskin.’ Of course, circumcision has also been ‘a major part of the ritual for such religions as Judaism, Christianity and Islam’, and as Hutson noted, ‘it is probably not accident that all of these arose in the Middle East.’ Today, circumcision is carried out not only for religious reasons but also, and importantly, for secular reasons, such as ‘the father’s desire for the baby to look like himself’ which is one of the most common reasons, as well as a fear of the locker room, wherein a boy would have a penis that looks different from that of those around him. For example, a 1987 article found that the most popular reason (46%) for circumcision ‘was wanting our son to resemble other males’. Likewise, a 2014 study published in the Pediatric Surgery International found that little has changed. In this study, we learn that the most common reasons for circumcision were ‘to be like dad’ (69%) and social acceptance among peers (69%), and the other reasons included health and in only 11% of cases were religious reasons given for routine neonatal circumcision in the hospital setting. Indeed, in a 2015 study published in The Journal of Perinatal Education, the reasons for circumcision remain similar; '[P]arents choose circumcision for their newborn sons for the child to have the same appearance as his father, to reduce his risk for infection, and because of beliefs about hygiene.' At bottom, then, it must be admitted that ‘a man’s perception of his genitalia has a significant effect on self-esteem and sexual identity’ which is why it is important that clinicians consider the question of aesthetics with regard to circumcision decisions.

CIRCUMCISION RISKS AND AESTHETIC CONSIDERATIONS
Given that ‘circumcision is the most frequently performed operation in the world,’ in addition to the influence on ‘self-esteem and sexual identity’, it seems valuable and important to consider the impact of the operation. From the outset, it should be recalled that the overall complication rate of 1.5% is low; however, as Schröder notes, “given the number of circumcisions performed worldwide, the number of affected children is enormous.”

In a survey completed by the National Organization to Halt the Abuse and Routine Mutilation of Males, respondents reported wide-ranging physical consequences from their circumcisions. Among the most significant consequences were prominent scarring (33%), insufficient penile skin for a comfortable erection (27%), erectile curvature from uneven skin loss (16%), pain and bleeding upon erection/manipulation (17%), painful skin bridges (12%) and other, e.g. bevelling deformities of the glans, meatal stenosis and recurrent nonspecific urethritis (20%).

Admittedly, this data is likely biased insofar as the study was conducted by an organization that has the explicit mandate of putting an end to routine neonatal circumcision. But what is valuable in this list is a series of reasons, commonly presented, against circumcision. Then the risks of circumcision are prominent scarring, insufficient penile skin for a comfortable erection and erectile curvature. Some of these reasons are more physical than aesthetic, but it is difficult to distinguish between the two, especially for a man in whom his penis has provided challenges to his self-esteem and sexual identity.
When we think about circumcision complications, we ought to move beyond the merely functional ‘does the penis still work?’ and towards other adjacent or orthogonal considerations, for instance, aesthetics. I argue, it would be advantageous to begin to think through the aesthetics of circumcision, especially given how frequent the reasons for circumcision are, in one sense or another, aesthetic, for instance, the circumcised penis looks better than the uncircumcised penis or for a son to look like his father and/or brothers. Although the latter reason may speak to community, it is also an aesthetic argument, which is to say, about appearances.

**SCARS**

Circumcisions, as we likely know, are not uniform; that is, not all circumcised penises look the same, even though they will look similar. There are different methods for circumcision, which will produce different results, at least aesthetically speaking. Gérard Zwang, for instance, notes that ‘the scar created by ritual circumcision, practiced in a workmanlike manner by non-doctors—be they mohels or barbers—is usually unsightly, torturous, and irregular, especially if it has suppurated.’ Zwang’s concern is ritual circumcision, but many of these same thoughts appear in critiques of medical circumcision. Nonetheless, what remains true is that circumcision does affect the aesthetics of the penis — even arguments for circumcision are often about improving upon the apparent ugliness of the uncircumcised penis.

In the cases of medical circumcisions, there are a few methods that have become commonplace, namely, the Mogen clamp, the Gomco clamp and the Plastibell, as well as less common modes such as the Sheldon clamp, which produces a guillotine-type circumcision. Given these different tools, it stands to reason that circumcision will not be uniform. Likewise, it has been observed that although the ‘many techniques of circumcision have a common goal: to remove equal amounts of inner and outer epithelial preputial tissue in a rapid, minimally traumatic and haemostatic fashion’, it must be admitted that there is a ‘fairly high [complication] rate (1.5 to 15%), [which] reflects the fact that the procedure is often performed by an inexperienced individual without attention to basic surgical principles.’ Incidentally, the Canadian newspaper, The Globe and Mail, reported that ‘few, if any, jurisdiction in Canada require physicians to undergo formal training before performing circumcision.’

Needless to say, given these dynamics, it is not surprising that circumcision results vary and complications do happen. The circumcision scar may appear in different places along the penis; for instance, one survey noted that one respondent had the scar close behind the glans, whereas the other’s scar was 25 mm back from it (Fig. 11.1). Additionally, although it is true that ‘the Gomco clamp and the Plastibell devices produce an even circular cut’, it must also be acknowledged that ‘if applied crookedly can result in cosmetic problems.’ Research has shown that the Gomco clamp has an overall complication rate of 1.9% and that the Plastibell’s overall complication rate range from 2.4% to 5%. In what follows, I focus on a few of these cosmetic problems, specifically missing frenulum, skin bridges or adhesions, two-toned and pigmentation variation and damage to the glans penis.

**Missing Frenulum**

A frenulum is ‘a small fold of integument or mucous membrane that limits the move of an organ or part’, and in the case of the penis, ‘the frenulum tethers the
foreskin and brings it back into position following retraction. The frenulum is continuous with the ridged band, which is a highly innervated pleated tissue just inside the opening of the foreskin. The frenulum and ridged band may have the highest concentration of fine-touch and other specialized neuroreceptors in the male body.\(^\text{22}\) (Figs. 11.2 and 11.3).

As such, the frenulum is often described as the king of all sensitive areas\(^\text{23}\) or as the so-called ‘G-spot’ of males,\(^\text{24}\) which is why it so often appears in sex advice columns in magazines and sex manuals. More specifically, ‘the frenulum is, by design, a little on the short side, so that during an erection and the swelling of the glans there is a pull on the band.’\(^\text{23}\) Although not necessarily an aesthetic concern, for many, it is most certainly a sexual and erotic concern.

Importantly, the frenulum is not removed during all circumcisions, as O’Hara and O’Hara note, ‘the tip of the foreskin, and some or all of the frenulum, are routinely removed as part of circumcision.’\(^\text{25}\) Likewise, Hammond and Carmack note that ‘the highly erogenous frenulum, often preserved in adult circumcision, is frequently ablated in neonatal circumcision due to the smaller size of the undeveloped penis.’\(^\text{26}\) Neonatal circumcision, thus, presents an interesting aspect to the ongoing debates about circumcision. It would seem that more care is taken with the adult penis, if we accept the claims of Hammond and Carmack, which

![Image of intact frenulum](https://upload.wikimedia.org/wikipedia/commons/5/54/Image_of_frenulum.jpg)
undoubtedly has an effect and influence on self-esteem, aesthetics and sexuality.

**Skin Bridges**

Ponsky and colleagues\(^{27,28}\) noted, ‘penile adhesions are common after circumcision’ and found that 28% of the boys they evaluated had some kind of penile adhesion, including skin bridges. Of the 254 boys 25 were referred for evaluation of penile adhesions, skin bridges, or other circumcision related issues.\(^{28}\) Gerharz and Haarman\(^{29}\) note that one ‘adverse result of circumcision is the formation of cutaneous bridges between the glans penis and the penile shaft’ and explain that ‘prominent skin bridges are aesthetically disturbing and may lead to tethering of the erect penis, with pain or penile curvature.’

In Fig. 11.4, the skin bridge is relatively minor and is mostly visible because of the erect state. However, the skin bridge may create discomfort to and/or curvature of the penis. The skin bridge thus shows a deviation from the norm of a circumcised penis or an ideal circumcised penis. Romberg\(^{30}\) explains that a skin bridge ‘is a complication in healing of the wound, by which a piece of skin from the shaft of the penis has become attached to the glans, or another point along the shaft, forming a “bridge” that must be surgically corrected.’

**Two-Toned and Pigmentation Variations**

One additional aesthetic concern, for some men, is what might be understood as a ‘two-toned’ penis, wherein the penis has two distinct colours, often divided by the circumcision scar (Figs. 11.5–11.7). This two-toned penis may not be an ideal one, and it may be considered an ugly or aesthetic concern for some men. In a survey completed by National...

**FIG. 11.5** Toned pigmentation and visible scar in flacid penis. (Source: https://upload.wikimedia.org/wikipedia/commons/0/06/Circumcised_flaccid.jpg)
Organization of Restoring Men, UK, 74% of the respondents were dissatisfied with the appearance of their circumcised penises, and particularly, 26% complained about the variation in skin colour. In the cases shown in Figs. 11.5–11.7, the penis is clearly functional; indeed, in Fig. 11.7, an erect penis is presented (with the frenulum intact). In each case, the circumcision scar is clearly visible. This scar, although likely not of concern for many, is certainly a concern for some; one respondent in a survey explained, ‘the physical scar is hideous, but the emotional scar equates to rape’. We should not be quick to dismiss these attitudes or ideas because for these men, they are genuinely held beliefs.

The Glans
Perhaps one of the most extreme examples of scarring and aesthetic concerns would be the example of the amputation of the glans penis, which is recognized as a rare circumcision complication. One case study notes that ‘the Sheldon clamp was placed over the prepuce, and the foreskin was pulled through the clamp and crushed. A scalpel was used to excise the prepuce. It was immediately recognized that the distal third of the penile glans had been surgically amputated.’ Another study notes a similar result in six cases that used the Mogen clamp. The Sheldon and Mogen clamps, unlike the Plastibell or the Gomco clamp, do not have a glans protective mechanism that minimizes its inclusion and injury during circumcision.

In their work, Salle and colleagues observed that Glans amputation during neonatal circumcision is a potentially devastating complication that appears to be particularly associated with the use of the Mogen clamp. They proposed that glans amputation can be prevented by careful preparation of the foreskin with complete lysis of ventral preputial adhesions before the placement of the clamp in order to avoid traction and inadvertent entrapment.

To be certain, complications do not arise with the Mogen or Sheldon clamp alone. One case study speaks of a child (4 years) who ‘had had a Plastibell circumcision 10 days previously’ and that ‘he had rested his penis on the toilet bowl, when a large wooden seat fell on the glans where the Plastibell ring was. This resulted in traumatic amputation of the glans.’ In such cases, then, undoubtedly, aesthetic considerations will remain and will need to be attended to. There will be scars from the reattachment of the glans (if possible), or there will be a noticeable absence of a part of the glans.

CONCLUSION: AESTHETICS MATTER
While the measure of a good circumcision might well be functionality, it is important that we take into account the aesthetic concerns. Brennan notes that ‘getting “botched” is a persistent anxiety of our augmentation-by-surgery age’, and although the incidence of circumcision complications is minimal, it is not insignificant.
especially with regard to self-esteem and sexual identity, as well as the perspectives and ideas of others, which, of course, have an influence on self-esteem. There is, of course, a significant body of scholarship that has noted, ‘thoughts about one’s body, including thoughts specific to one’s own genitals, have been linked to men’s sexual function.’ Unsurprisingly, then, ‘the role of body image in men’s sexual lives extends also to their penis specifically’; however, ‘genital body image has typically focused on appearance of the penis or penis length.’ Indeed, as Bossio and Pukall note, ‘little research has empirically explored the potential role of circumcision status in a man’s body appraisal of his body image, particularly as body image relates to sexual functioning.’ I certainly agree with Bossio and Pukall, but as this chapter has sought to demonstrate

---

**FIG. 11.7** Prominent color change on circumcised penis, with two circumcision scars following a second circumcision to correct inadequate foreskin removed after initial circumcision. The frenulum has been trimmed but retained. (Source: https://commons.wikimedia.org/wiki/Category:Circumcised_human_penis#/media/File:Circumcisedtwice.jpg)
that not all circumcisions are the same, we need to focus not only on circumcision but also on the quality of circumcision, which includes taking into account aesthetic or cosmetic matters, as well as sexual and functional concerns. As such, circumcision complications should not be treated lightly, even if the penis is functional. We might do well to think about the adjacent concerns: aesthetics, sexuality and self-esteem.

ACKNOWLEDGMENT
This research was undertaken, in part, thanks to funding from the Canada Research Chairs program.
